Abstract

This paper aims to analyse the effect of trade facilitation on sectoral trade flows. We use data from the World Bank's Doing Business Database on the fees associated with completing the procedures to export or import goods in a country, on the number of documents needed and on the required time to complete all the administrative procedures to import and export. An augmented gravity equation is estimated for 13 exporters and 167 importers using a number of estimation techniques, namely OLS, PPML and the Harvey model. A common result is that trade flows increase by lowering transport costs and the number of days required to trade. The outcome supports multilateral initiatives, as that in the WTO, which encourages countries to assess their trade facilitation needs and priorities and to improve them. The measures adopted will not only benefit the country that improves trade facilitation, but also its trading partners.

THE EFFECT OF TRADE FACILITATION ON SECTORAL TRADE

1. INTRODUCTION

The aim of this paper is to shed some light on the relationship between trade facilitation and trade flows, and to evaluate the potential benefits of trade facilitation in terms of boosting exports. This issue is of growing interest in the trade policy debate since trade facilitation has been included in the Doha Development Agenda. The mandate for the World Trade Organization (WTO) negotiations on trade facilitation was adopted in July 2004. Special and differential treatment, and technical assistance and capacity building, are integral parts of the negotiations, and are linked to the final outcome. The Mandate encourages WTO members to assess their trade facilitation needs and priorities, mainly those of developing and the least-developed countries. Any trade facilitation efforts made by developing countries to accomplish the WTO mandate will unquestionably have a positive effect on trade volumes, and will help to improve economic development and living standards. While other trade costs (tariffs and non-tariff barriers) have fallen as a result of WTO trade negotiations and regional integration agreements, transaction costs related to cross-border trade procedures have become relatively more important.

The measurement and quantification of the potential benefits of trade facilitation have only been investigated recently. Although increasing attention has been paid to this issue, no consensus has been reached regarding the trade policy discourse on the definition of trade facilitation. In most cases, two ways of defining this concept have been used. On the one hand, trade facilitation in a narrow sense includes the so-called “at the border procedures”, such as customs documentation or the time involved in crossing a border. On the other hand, trade facilitation in a broad sense also includes some “inside the

border" elements, such as institutional quality, regulatory environment and service infrastructure.

Since the effect of institutional quality and regulatory environment on trade has already been investigated elsewhere,[1] in this work we focus on the narrow definition and consider only "border" related elements. In this line, trade facilitation is understood as the reduction, or at least the simplification, of "at the border procedures", comprising a number of documents and the time involved in crossing the border, as well as the transaction cost incurred. In addition, we consider the Technological Achievement Index (UNDP, 2001) as a proxy for services infrastructure, whose composition includes several indicators of service infrastructure.

As far as we know, the effects of trade facilitation on trade volumes at a disaggregated level have not yet been investigated. The innovation of the paper consists of using recent methodological developments to address the issue of trade facilitation at the sectoral level.

The paper is arranged as follows. The most recent literature on trade facilitation is reviewed in Section 2. Section 3 describes the selection of countries, data sources and variables. Section 4 presents the estimation strategy and main results, and a final section summarises the main findings.

[1] Levchenko (2007).

2. LITERATURE REVIEW

In recent years, growing interest in the study of the beneficial effects of trade facilitation has been shown. However, the approaches used are far from uniform in terms of the definition of trade facilitation and the empirical approach used.

In relation to the definition of trade facilitation, Wilson, Mann and Otsuki (2003, 2005) considered a broad definition of trade facilitation, and quantified the impact of four different measures (port efficiency, customs environment, regulatory environment and e-business usage). As an alternative, Engman (2005) used the WTO definition of trade facilitation (the simplification and harmonisation of international trade procedures) by paying attention only to what happens around the border. Other authors[2] focused, instead, on the effects of single measures of trade facilitation (information technology, port efficiency, institutions' quality).

Two main modelling approaches have been used. On the one hand, several investigations use the gravity model of trade augmented with "trade facilitation" variables. In this line, Wilson, Mann and Otsuki (2003, 2005) estimated a gravity model of trade augmented with the above-mentioned trade-facilitation variables for a group of countries in the Asia-Pacific region and for a sample of 75 countries. Soloaga, Wilson and Mejía (2006) used a similar methodology and data, but focused on Mexican competitiveness. However, Djankov, Freund and Pham (2006) used the World Bank's Doing Business Database, as we do in this paper, but focused only on the effects of time delays in the exporting country. Finally, Nordas, Pinali and Grosso (2006) centred on how time delays affect the

[2] See Wilson, Mann and Otsuki (2003, 2005) for a more detailed review of earlier work on single measures of trade facilitation.

probability to export and the export volumes for imports from Japan, Australia and the United Kingdom.

On the other hand, several institutions and authors (UNCTAD, 2001; OECD, 2003; Dennis, 2006; Decreux and Fontagne, 2006) used a computable general equilibrium model to estimate the effect of a composite index of trade facilitation on trade flows.

Although several data sets and estimation methods have been utilised within the context of these two approaches, the results reveal significant and positive effects on trade flows in most cases.

This paper mainly differs from existing literature in that it uses disaggregated trade data (4-digit level), which not only allow us the possibility to analyse the differential effect of trade facilitation on sectoral trade flows, but also the inclusion of three different measures of trade facilitation for exporter and importer countries separately.

3. SELECTION OF COUNTRIES, DATA, SOURCES AND VARIABLES

3.1 Country selection

Since the amount of data available at the sectoral level is huge, and we wish to investigate the effect of trade facilitation on sectoral trade at a broad level, it is important to select a representative sample of countries. With this aim, we use a revealed comparative advantage (RCA) index in order to classify countries according to their specialisation and pattern of trade. The RCA is calculated according to Balassa's (1965) measure of relative export performance by country and industry to determine which goods countries are specialised. The index is defined as a country's share of world

exports of a given good divided by its share of total world exports, as expressed in Equation (1):

$$\boldsymbol{RCA_{ik}} = \frac{\boldsymbol{X_{ik}} / \boldsymbol{X_{wk}}}{\boldsymbol{X_{iN}} / \boldsymbol{X_{wN}}} \cdot 100 \qquad (1)$$

where RCA_{ik} is the RCA index of commodity k for country i, X_{ik} is the value of exports of commodity k by country i, X_{wk} is the value of world exports of commodity k, X_{iN} is the value of exports of all commodities by country i, and X_{wN} is the value of world exports of all commodities. The RCA index is calculated for 65 countries (Appendix, Figure A.1) which represent more that 70% of world trade. A ranking of the first ten industries with the highest positive RCA values is drawn up for each country for the year 2000.[3] The Rauch Classification of Goods is used to determine whether countries are specialised in goods traded in an organised exchange (homogeneous), in reference-priced goods or in differentiated goods (Rauch, 1999).

According to Equation (1), country i has a comparative advantage in exporting commodity k when RCA_{ik} is greater than one. The patterns of specialisation indicate that developing Asian countries (China, India, Nepal and Pakistan) are specialised mainly in differentiated products, whereas developing African countries (Egypt, Mozambique and Sudan) are specialised in homogeneous goods. A number of high-income countries are specialised mainly in differentiated and reference-priced products, whereas others, Canada, France, Ireland, Hong Kong, Japan, Singapore, Switzerland-Liechtenstein, the United Kingdom and the United States, tend to be specialised in high-technology sectors. Finally, a number of medium-income countries that are mainly Mediterranean, Central-

[3] Results are available upon request from the authors.

Eastern European and Latin American, are specialised in differentiated and reference-priced goods.

A classification matrix was constructed to choose a representative sample of countries for the sectoral analysis. Classifications by country (developed and developing countries) and by commodity (Rauch, 1999: differentiated, reference-priced and homogeneous) were considered. Information obtained from the RCA was used to determine whether countries were specialised in differentiated, reference-priced or homogeneous goods. For example, when a country was relatively more specialised[4] in differentiated goods (ranked in the 10 most exported goods) than in reference-priced or homogenous goods, it was then considered to be specialised in differentiated goods. At least one representative country was chosen from each group (Table A.1, in bold). However, when more than ten countries were classified in the same group, two representative countries were chosen for the empirical analysis. The countries chosen per continent were the following: Bolivia, Brazil and Chile for Latin America; the United States for North America; China and Japan for Asia; the Czech Republic, Germany, Spain and the United Kingdom for Europe; Ghana and South Africa for Africa; and Australia for Oceania.

3.2 Data and sources

Bilateral trade data by commodity were obtained from Feenstra, Lipsey, Deng, Ma and Mo (2005). The level of disaggregation chosen was 4-digit SITC. The sample of countries considered included 13 exporters and 167 importers in the year 2000 (Appendix, Tables A.1 and A.2). The final sample included 146 categories with

[4] Specialisation can be defined as "producing more than you need of some things, and less of others, hence specialising in the first". Definition obtained from Deardorff's Glossary of International Economics (http://www-personal.umich.edu/~alandear/glossary/).

homogeneous goods, 349 categories with reference-priced goods, and 694 categories with differentiated goods.

Distance between capitals, common official language and the colonial dummy were taken from CEPII.[5] Income variables were from the World Development Indicators (2005) Database, and the World Integrated Trade Solution (WITS) was the source of tariffs. The Technological Achievement Index (TAI) was from UNPD (2001). The TAI was constructed using indicators of a country's achievements in four dimensions (creation of technology, diffusion of recent innovations, diffusion of old innovations and human skills), thus providing a summary of a society's technological achievements. Finally, trade facilitation variables were from the World Bank's Doing Business (2006) database. This database was recently created by the World Bank and compiles procedural requirements for exporting and importing a standardised cargo of goods. Since trade facilitation variables are the main interest of this research, we considered it appropriate to present a more detailed description concerning the data collection. Doing Business compiles procedural requirements for exporting and importing a standardised cargo of goods. Every official procedure for exporting and importing the goods is recorded (from the contractual agreement between the two parties to the delivery of goods) along with the time and cost necessary for completion. All documents required for the clearance of the goods across the border are also recorded. For exporting goods, procedures range from packing the goods at the factory to their departure from the port of exit. For importing goods, procedures range from the vessel's arrival at the port of entry to the

[5] The dist_cepii file was taken from http://www.cepii.fr/anglaisgraph/bdd/distances.htm. The language variable (comlang_off) takes the value of one when two countries share a common official language, zero otherwise and distances are calculated following the great circle formula, which uses latitudes and longitudes of the most important cities/agglomerations (in terms of population).

cargo's delivery at the factory warehouse. Local freight forwarders, shipping lines, customs brokers and port officials provide information on required documents and costs, as well as the time to complete each procedure. To make the data comparable across countries, several assumptions about the business and the traded goods are used. The main assumptions refer to the business and types of goods traded. The business has to be located in the country's most populous city, and it must have 200 employees or more. It is a private, limited liability company that does not operate within an export processing zone, or an industrial estate with special export or import privileges. The business must be domestically owned with no foreign ownership and exports more than 10% of its sales.

The traded product has to travel in a dry-cargo, 20-foot, full container load, is not hazardous, and does not include military items. In addition, it does not require special conditions for transport, like refrigeration, and does not require any special phytosanitary or environmental safety standards other than accepted international standards. Finally, the product falls under the following Standard International Trade Classification (SITC) Revision categories: SITC 65 (textile yarn, fabrics and made-up articles); SITC 84 (articles of apparel and clothing accessories) or SITC 07 (coffee, tea, cocoa, spices and manufactures thereof).

Cost is recorded as the fees levied on a 20-foot container in US dollars. All the fees associated with completing the procedures to export or import goods are included. These, in turn, include costs of documents, administrative fees for customs clearance and technical control, terminal handling charges and inland transport. The cost measure does not include tariffs or trade taxes. Only official costs are recorded.

Table 1 presents a statistics summary of the trade facilitation variables: the average, maximum and minimum values of cost to export, cost to import, time to export, time to import, and documents to export and documents to import for the selected sample are shown. Several patters are observed. Transporting goods from factory to ship (exports) is relatively cheaper than transporting them from ship to factory (imports). The variation of costs across countries is also larger for imports, with an average cost of 333$ per container in Singapore and 4565$ per container in Zimbabwe. In terms of time, taking products from the factory to the port only takes 6 days on average in Germany, whereas it takes 31 days in South Africa. Taking products from the port to the factory takes only 3 days in Singapore, but 139 days in Uzbekistan.

3.3 Variables

Two types of variables are used. Income, geographical, cultural and integration dummies and trade facilitation variables, which vary across countries, whereas tariffs, high-technology and sectoral dummies vary across sectors. The high-technology dummy is based on the OECD (2001) and Eurostat (1999) classifications. The OECD's classification is based on R&D intensities, and Eurostat suggests a higher disaggregation level and defines commodities using the Standard International Trade Classification (SITC) Revision 3 at the 4-digit level. Concordances from the Centre for International Data at UC Davis between SITC Revision 2 and Revision 3 are used since trade data are defined according to SITC Revision 2. Table A.3 presents the list of high-technology sectors considered to create the high-technology dummy. Finally, sectoral dummies are based on Rauch (1999) and were obtained from the Jon Haveman's International Trade

Data web page.[6] Table A.4[7] provides a summary of the data and sources used in this paper.

4. EMPIRICAL ANALYSIS

4.1. Model specification

One of the main devices used to analyse the determinants of international trade flows is the gravity model of trade. Recently, some authors have referred to this model as the "workhorse" of empirical trade studies (Eichengreen and Irwin, 1998; Cheng and Wall, 2005). A (traditional) gravity equation augmented with trade facilitation variables is specified and estimated for disaggregated data. The estimated equation is:

$$\begin{aligned}\ln X_{ijk} &= \alpha_0 + \alpha_1 \cdot \ln Y_i + \alpha_2 \cdot \ln Y_j + \alpha_3 \cdot Adj_{ij} + \alpha_4 \cdot Land_i + \alpha_5 \cdot Land_j + \alpha_6 \cdot MERC + \\ &+ \alpha_7 \cdot NAFTA + \alpha_8 \cdot CAN + \alpha_9 \cdot EU + \alpha_{10} \cdot EMU + \alpha_{11} \cdot ECOWAS + \alpha_{12} \cdot CEFTA + \\ &+ \alpha_{13} \cdot \ln Dist_{ij} + \alpha_{14} \cdot Lang_{ij} + \alpha_{15} \cdot Colony_{ij} + \alpha_{16} \cdot TAI_i + \alpha_{17} \cdot TAI_j + \alpha_{18} \cdot \ln Tariffs_{ik} + \\ &+ \alpha_{19} \cdot \ln TC_i + \alpha_{20} \cdot \ln TC_j + \alpha_{21} \cdot ET_i + \alpha_{22} \cdot ET_j + \alpha_{23} hightech_k + \alpha_{24} \cdot \hom_k + \\ &+ \alpha_{25} \cdot ref_k + \alpha_{26} \cdot DP + \varepsilon_{ijk}\end{aligned} \quad (2)$$

where *ln* denotes natural logarithms.

X_{ijk} denotes the value of exports of commodity k from country i to j; Y_i and Y_j are income in the exporter's market and the destination market, respectively; Adj_{ij} is a dummy that indicates whether the trading partners are contiguous; $Land_i$ and $Land_j$ take the value of 1 when the exporting or importing countries are landlocked, respectively, and zero otherwise. MERC, NAFTA, CAN, EU, EMU, ECOWAS and CEFTA are integration dummies that take a value of one when the trading partners belong to a given agreement, otherwise values are zero. The integration agreements considered are: Mercosur (MERC); the North American Free Trade Area (NAFTA), Andean Community (CAN),

[6] http://www.macalester.edu/research/economics/PAGE/HAVEMAN/Trade.Resources/TradeData.html

[7] Table A.8 in Appendix. The first column lists the variables used for empirical analysis; the second column outlines a description of the variables, and the third column shows the data sources.

the European Union (EU), the Economic and Monetary Union (EMU);[8] the Economic Community of West African States (ECOWAS) and the Central European Free Trade Agreement (CEFTA).

$Dist_{ij}$ is the geographical great circle distance in kilometres between the most important cities (in terms of population) of country *i* and *j*. $Lang_{ij}$ is a dummy for countries sharing a common official language. $Colony_{ij}$ is a dummy that takes the value of 1 when trading partners have had a colonial link at any time. TAI_i and TAI_j are Technological Achievement Indices in the exporting and importing country. $Tariff_{ik}$ is the simple average effectively applied tariff for all countries importing each commodity from the 13 exporters. TC_i and TC_j measure the cost to both export and import, respectively. ET_i and ET_j denote the time to export and import, respectively (first specification). Alternatively, a second specification with the number of documents needed to export and import will be estimated. Finally, a third specification will include "easy to trade" indices instead, constructed as simple averages of the logarithm of time to export/import and the logarithm of the number of documents to export /import. $High\text{-}tech_k$ is a dummy that takes the value of 1 when the commodity is a high-technology commodity (Appendix, Table A.3). Hom_k takes the value of 1 when a commodity is homogeneous, otherwise the value is zero, whereas ref_k takes the value of 1 when a commodity is reference-priced, according to the conservative Rauch Classification (1999).[9] The *DP* dummy takes the value of one when the exporting country is a developed country. Finally, ε_{ijk} is the error term which is assumed to be independently and identically distributed.

[8] Greece is also considered, since the Greek government announced on 15 January 2000 the drachma-euro exchange rate with which Greece would enter the third stage of EU Economic and Monetary Union (EMU) on 1 January 2001.

[9] The "conservative" classification minimises the number of 4-digit commodities that are classified as either organised-exchange or reference-priced.

Equation (2) is estimated using the Harvey model[10], and both the Ordinary Least Squares (OLS) and Pseudo Poisson Maximum Likelihood (PPML) methods. The Harvey model and the PPML estimator are used as alternative options to control heteroscedasticity. The Harvey model controls multiplicative heteroscedasticity, whereas the PPML method controls more general forms of heteroscedasticity. Santos-Silva and Tenreyro (2006) pointed out that log-linearisation of the gravity model of trade leads to inconsistent estimates when heteroscedasticity is present. As a consequence, the role of geographical proximity and links is overstated. In addition, the zero values in the dependent variable cannot be considered in the OLS estimation. Since the database of Feenstra et al. (2005) includes only sectors with positive trade volumes, the problem of zeros in the dependent variable is not an issue in our empirical estimation. However, the presence of heteroscedasticity could bias coefficients obtained in OLS regressions. In fact, the results of the White's Test indicate that the error term is heteroscedastic.

In line with the recent developments concerning the specification of the gravity equation, a second version of the model is estimated. Anderson and van Wincoop (2003) showed that the key aspect of the gravity model is the dependence of trade on bilateral and multilateral resistance factors. Theoretically, this is because these models are determined by relative trade barriers and not only by absolute trade barriers between the exporter and the importer country. In order to control multilateral resistance factors, dummies for exporters and importers are added to the empirical model. The model specification is:

[10] Harvey's model of multiplicative heteroskedasticity has been estimated since it is a very flexible model that includes most of the useful formulations as special cases. The general formulation is $\sigma_i^2 = \sigma^2 \exp(z_i'\alpha)$.

$$\begin{aligned}\ln X_{ijk} &= \delta_i + \lambda_j + \alpha_0 + \alpha_1 \cdot Adj_{ij} + \alpha_2 \cdot MERC + \alpha_3 \cdot NAFTA + \alpha_4 \cdot CAN + \\ &+ \alpha_5 \cdot EU + \alpha_6 \cdot EMU + \alpha_7 \cdot ECOWAS + \alpha_8 \cdot CEFTA + \alpha_9 \cdot \ln Dist_{ij} + \\ &+ \alpha_{10} \cdot Lang_{ij} + \alpha_{11} \cdot Colony_{ij} + \alpha_{12} \cdot Tariffs_{ik} + \alpha_{13} \cdot \ln TC_i + \\ &+ \alpha_{14} \cdot \ln TC_j + \alpha_{15} \cdot ET_i + \alpha_{16} \cdot ET_j + \alpha_{17} \cdot hightech_k + \alpha_{18} \cdot \hom_k + \\ &+ \alpha_{19} \cdot ref_k + \alpha_{20} \cdot DP + \varepsilon_{ijk}\end{aligned} \quad (3)$$

where ln denotes natural logarithms. δ_i denotes exporter dummies and λ_j represents importer dummies.

However, since the trade facilitation variables are country specific, the effect of cost to export/import and the time to export/import cannot be directly evaluated by estimating Equation (3). Therefore, we estimate two versions of Equation (3). The first includes only country dummies for exporters and the traditional country-specific variables for importers (income and trade facilitation variables); the second includes only dummies for importers and country-specific variables for exporters. A way of validating the results is to observe whether they are robust for the different specifications (2) and (3) and the estimation techniques used. Alternatively, Equation (3) could be estimated by adding exporter and importer effects, and by restricting the trade facilitation variables to obtain the same coefficients for both exporter and importer (e.g. $ET_{ij}=ET_i*ET_j$).

4.2. Main results

Table 2 shows the main estimation results obtained for the trade facilitation variables. Two versions of the gravity model are estimated using OLS, PPML and the Harvey model. Columns two, four and six refer to the "traditional" gravity equation with country-specific variables (Equation 2), whereas columns three, five and seven show the estimates of the gravity equation with the exporter/importer effects added (Equation 3). The full regression results are shown in the Appendix (Tables A.5-A.7). Three specifications are considered in relation to the trade facilitation variables. Whereas the first includes cost and time variables, the second includes costs and the number of documents, and the third incorporates cost and '"easy to trade". The estimates for cost to import and cost to export always have the expected negative sign and are significant in all cases. Both the OLS and the Harvey Model estimates show a smaller effect of transaction cost on trade than the Poisson results, and are more stable across specifications (traditional versus new). The magnitude of the elasticities varies between -0.22 and -0.70 and between -0.04 and -0.37 for exports and imports, respectively. The Harvey model offers the more conservative estimates. These elasticities can be translated in monetary terms by evaluating the marginal effect at the average values of transaction costs (C) and sectoral exports (X):

$$\frac{\partial X}{\partial C_{i(j)}} = \alpha_{13(14)} * \frac{\overline{X}}{\overline{C}_{i(j)}} \qquad (4)$$

where the X and C bars denote average values, and α_{13} and α_{14} respectively denote the estimated coefficients in Equation (3) above using the Harvey model.

When considering the more conservative estimates obtained when estimating Equation (3), which are those obtained in the first specification, a decrease of one US dollar in the cost to export a 20-foot container yields an increase in exports of almost 11 thousand US

dollars (0.29*25100T$/712). Regarding importers, the effect is somewhat smaller: a decrease of one US dollar in the cost to export a 20-foot container yields an increase in exports of almost 1 thousand US dollars (0.04*25100T$/1066).

In relation to the time for export/import variables, the estimates are always negative, apart from time for exports in the PPML estimation. A reduction in time for exports has a lesser effect on exports than a reduction in time for imports. According to the Harvey estimates, the effect of a one-day reduction on the average days required to export a good is an increase of exports of 0.22% [(1/18)*0.04], whereas the effect of a one-day reduction on the average days needed to import a good is an increase of exports of 0.83% [(1/22)*0.15].

The estimates for the number of documents needed for exports and imports indicate that the variables are not always significant across specifications. However, both are significant and show a negative effect on exports in the Harvey specification with exporter or importer dummies. The effect of reducing the number of documents (one document less) on trade is higher for documents needed for export (an increase in exports of 2.6%) than for documents needed for imports (an increase in exports of 0.25%). To summarise in terms of time, a time reduction to import a good has a greater effect on exports than a time reduction to export a good. On the other hand, a reduction in the number of documents to import has a lesser effect on exports than a reduction in the number of documents to export.

A way of combining both effects is to include a mixed variable, what we call “easy to trade”. It is calculated as a simple average of both time and the number of documents.

The results indicate that the "easy to import" variable has a slightly higher effect on exports than the "easy to export" variable.

A policy implication will be that any efforts to improve trade facilitation in the trading partners will have positive effects on exports and therefore multilateral initiatives, as that in the WTO, are supposed to have positive effects on not only the country that improves trade facilitation, but also on its trading partners.

Table 3 presents the results when a quadratic term for the time variable is added, allowing the effect of trade facilitation on exports to be non-linear. The added quadratic term is statistically significant, which indicates that the elasticity of trade in relation to time decreases with the number of days needed to export/import. Additional days will have smaller marginal effects when time requirements are already high. We have calculated a "turning point" that indicates the time requirement (number of days for export/import) for which the lowering of border delays no longer has a positive effect on exports. Waiting more than 11 days and 74 days for exports and imports, respectively, at the border will no longer have a negative effect on exports (estimates in the last column have been used to compute these turning points).

Table 4 shows the results obtained when the model is estimated using only exports for the 3 SITC product categories considered as a dependent variable to collect data on trade facilitation variables (SITC 65: textile yarn, fabrics and made-up articles; SITC 84: articles of apparel and clothing accessories; or SITC 07: coffee, tea, cocoa, spices and manufactures thereof). The specification including cost and time variables is the most stable. The OLS and Harvey results are reassuring since the sign and significance of the coefficients on trade facilitation variables are similar to those found for all sectors (Table

2). The main difference is that the impact of transaction costs on exports almost doubled in comparison with the results for all industries. Similarly, a higher elasticity is found for the time to export, whereas the coefficients are almost the same for the time to import (OLS and Harvey results). The question whether the trade facilitation effect on exports can be generalised to other sectors is still open and requires further research.

Next, the two last rows of Table 2 show the estimated coefficients for the Technological Achievement Indices TAI_i and TAI_j. Both are significant and higher in magnitude for exporters than for importers[11]. If we consider that these indices could be a proxy for the services infrastructure, then the potential effect on trade flows is important given the relatively high magnitude of the coefficients (0.30 and 1.21 for importer and exporter TAI respectively, according to the Harvey-new-specification results), and by also taking into account the beta coefficients that show the relative importance of the explanatory variables (TAIs are second in order of magnitude after income variables). It is also worth noting that when the model was estimated for sectors SITC 65, 84 and 07 (Table 4) the estimated coefficients for both technological variables were not statistically significant.

Finally, the performance of the other variables in the model will be briefly discussed. Concerning the results obtained for the "theoretically justified" gravity model, both the OLS and Harvey results are very similar and stable across specifications. All the variables included in the regression are significant and present the expected sign, with the exception of the colonial ties and tariffs. With regard to regional integration, membership of MERC, NAFTA, CAN, EU, EMU and CEFTA has a positive effect on exports. The positive and significant high-tech dummy shows that technologically intensive goods are traded more than other goods, whereas the dummies for different types of goods indicate

[11] As obtained when using aggregated exports (Martínez-Zarzoso and Márquez-Ramos, 2005).

that trade in differentiated products is higher than trade in referenced and homogeneous goods. In relation to tariffs, the coefficient is positive and significant. This result was unexpected since protection is supposed to have a negative effect on trade. A possible explanation may be that the structure of world tariffs benefits exports from the 13 exporting countries included in the regression. Another explanation could be that exporters (developing countries) are using tariffs as a source of revenue. Therefore, they set up high tariffs in the products that are being exported.[12]

Beta coefficients are calculated to determine the relative importance of the different variables included in the model. In absolute values, the highest beta coefficients are for income, TAIs and geographical distance. Finally, the R-squared is around 0.25, significantly lower than that obtained when estimating aggregated data, but in line with previous literature.

Unlike the OLS and Harvey results, the PPML estimates indicate that EMU, ECOWAS, language and colonial dummies are positive and not significant, or that they have a negative sign and are significant. The result obtained of socio-cultural links having no effect (or a negative effect) on trade flows was unexpected since trade has been shown to increase with links (Rauch, 1999). Furthermore, the PPML results are less stable across specifications and show a worse performance in terms of forecasting accuracy (The inverse U-Theil index is lower for the PPLM estimations).

4.2. Robustness

[12] This is investigated by restricting the sample to developing countries as exporters to all the other countries. In this case, results show that the tariff coefficient takes a value of 0.42 in the OLS estimation, a value of 0.75 in the PPML estimation and a value of 0.36 in the Harvey estimation. When restricting the sample to developed countries as exporters to all the other countries, results show that the tariff coefficient takes a value closer to zero in the OLS (0.04) and Harvey (0.08) estimation and is not significant in the PPML estimation.

A number of robustness checks are presented in this section. Firstly, and based on Santos-Silva and Tenreyro (2006), a heteroscedasticity-robust RESET test was performed. The authors showed that by using aggregated exports, only the models estimated using the PPML regressions pass the RESET test. This test was performed by adding a regressor, constructed as $(x'b)^2$, where b is the vector of estimated parameters. The *linktest* available in STATA was used to test specification errors. The results showed that the variable square prediction was significant in all cases, indicating a misspecification of the PPML with sectoral data. Additionally, the inversed U-Theil criterion was used to compare models with different scales in the dependent variable. Higher values of the inverse U-Theil indicated that one particular model was preferred. According to this criterion, the Harvey model is better than Poisson in terms of forecasting accuracy.

Secondly, a number of interaction variables have been added to the basic specification (Equation 3), namely time for export/import is interacted with the high-tech dummy, the DP dummy and also with the homogeneous and referenced goods' dummies. The results (Table 5) indicated that exports were more time-sensitive when the products traded are technology-intensive. Exports of homogeneous and referenced price goods were less time-sensitive than exports of differentiated products, while developed countries exports were also more sensitive to time to export (dp*lxtime is negative). Moreover, exports among developing countries were more sensitive to time to import (dp*lmtime is positive).[13] More mixed results were obtained for the specification including the number of documents to export/import. Finally, the model was also estimated for each type of good separately. A negative (expected) effect of tariff barriers was found in the case of homogeneous goods.

[13] Results are available upon request from the authors.

5. CONCLUSIONS

In this paper, the effect of trade facilitation on international trade flows was evaluated using disaggregated trade data. A gravity model extended with trade facilitation variables was estimated and three different estimation techniques, namely OLS, PPML, and the Harvey model, were used. The OLS and Harvey results were very similar and stable across specifications and showed a better performance in terms of forecasting accuracy than the PPML results.

On average, and in terms of transaction costs, a decrease of one US dollar in the cost to export a 20-foot container yields an increase in exports of almost 11 thousand US dollars, whereas a decrease of one US dollar in the cost to export a 20-foot container yields an increase in exports of almost 1 thousand US dollars.

In terms of time, the effect of a one-day reduction on the average days required to export a good is an increase of exports of 0.22%, whereas the effect of a one-day reduction on the average days required to import a good is an increase of exports of 0.83%. However, the effect of time is non-linear since additional days will have smaller marginal effects on exports when time requirements are already high. Waiting more than 11 days and 74 days for exports and imports, respectively, at the border will no longer have a negative effect on exports. A time reduction to import a good has a greater effect on exports than a time reduction to export a good. On the other hand, a reduction in the number of documents to import has a lesser effect on exports than a reduction in the number of documents to export.

The enhancing effect on trade flows of a reduction in both the number of days and documents required to export/import differs across sectors (technology-intensive,

differentiated) and countries (developed/developing). Exports of technology-intensive goods are more time-sensitive. Furthermore, Exports of homogeneous and referenced price goods are less time-sensitive than exports of differentiated products, while developed countries exports are also more sensitive to time to export than developing countries exports.

Overall, the results indicate that multilateral initiatives, as that in the WTO, are potentially beneficial in terms of increasing trade. Trade facilitation efforts are supposed to have positive effects on not only the country that improves trade facilitation, but also on its trading partners.

Note: Countries are classified into three groups as follows: countries are arranged in order from higher to lower income levels (GDP per capita, PPP in 1999. Source: WDI, 2005), then an upper level of GDP is composed by calculating the average of the first half of the sample, and an inferior level by calculating the average of the second half. Commodities are classified according to Rauch (1999).

Table A.4. Variable descriptions and sources of data. Disaggregated analysis.

Variable	Description	Source
X_{ijk} : Exports from i to j of commodity k	Value of exports in thousands of US dollars in the year 2000	Feenstra et al. (2005)
Y_i : Exporter's income	Exporter's GDP, PPP (current international $)	World Bank (2005)
Y_j : Importer's income	Importer's GDP, PPP (current international $)	World Bank (2005)
Adj_{ij} : Adjacency dummy	Dummy variable = 1 if the trading partners share a common border, 0 otherwise.	CEPII (2006)
$Land_i$: Landlocked dummy	Dummy variable = 1 if the exporting country is landlocked, 0 otherwise.	CEPII (2006)
$Land_j$: Landlocked dummy	Dummy variable = 1 if the importing country is landlocked, 0 otherwise.	CEPII (2006)
MERC dummy	Dummy variable = 1 if the trading partners are members of MERC, 0 otherwise	
NAFTA dummy	Dummy variable = 1 if the trading partners are members of NAFTA, 0 otherwise	
CAN dummy	Dummy variable = 1 if the trading partners are members of CAN, 0 otherwise	
EU dummy	Dummy variable = 1 if the trading partners are members of EU, 0 otherwise	
EMU dummy	Dummy variable = 1 if the trading partners are members of EMU, 0 otherwise	
ECOWAS dummy	Dummy variable = 1 if the trading partners are members of ECOWAS, 0 otherwise	
CEFTA dummy	Dummy variable = 1 if the trading partners are members of CEFTA, 0 otherwise	
$Dist_{ij}$: Distance	Great circle distances between the most important cities in trading partners	CEPII (2006) http://www.cepii.fr/anglaisgraph/bdd/distances.htm
$Lang_{ij}$: Language dummy	Dummy variable = 1 if the trading partners share the same official language, 0 otherwise.	CEPII (2006)
$Colony_{ij}$: Colony dummy	Dummy variable = 1 if the trading partners have ever had a colonial link, 0 otherwise.	CEPII (2006)
TAI_i : Exporter's TAI	Technological variable	UNDP (2001), author's calculations
TAI_j : Importer's TAI	Technological variable	UNDP (2001), author's calculations
$Tariffs_{ik}$	Effectively applied rates in sector k	WITS (2006) http://wits.worldbank.org/witsnet/StartUp
TC_i: Exporter's transport costs	Transport costs (US$ per container)	Doing Business (2006)
TC_j: Importer's transport costs	Transport costs (US$ per container)	Doing Business (2006)
ET_i: Exporter's trade facilitation	Days for export, number of documents for export	Doing Business (2006)
ET_j: Importer's trade facilitation	Days for import, number of documents for import	Doing Business (2006)
High-tech dummy	Dummy variable = 1 when commodity is a high-technology commodity, 0 otherwise	Jon Haveman's International Trade Data http://www.macalester.edu/research/economics/PAGE/HAVEMAN/Trade.Resources
Hom_k dummy	Dummy variable = 1 when a commodity k is homogeneous, according to Rauch classification (1999), 0 otherwise	
Ref_k dummy	Dummy variable = 1 when a commodity k is reference-priced, according to the Rauch Classification (1999), 0 otherwise	Jon Haveman's International Trade Data

RMSE	1.62	1.62	1.6	1.62	1.6
Number of observations	149985	149985	160321	149985	160321

Notes: ***, **, *, indicate significance at 1%, 5% and 10%, respectively. Z-statistics are provided in brackets. The dependent variable is the natural logarithm of exports in value (thousands of US$). The pseudo-R2 in the output is obtained by computing 1 – LL (full model)/LL (constant only model), which in this case varies between 0.08 and 0.09. This is McFadden's pseudo-R2 and it may not be the best measure of fit. The VWLS (variance-weighted least squares) R2 is obtained by using the inverse of the estimated variances in the heteroscedastic model as weights in the corresponding regression model.

Notes: ***, **, *, indicate significance at 1%, 5% and 10%, respectively. Z-statistics are provided in brackets. The dependent variable is the natural logarithm of exports in value (thousands of US$). The pseudo-R2 in the output is obtained by computing 1 – LL (full model)/LL (constant only model), which in this case varies between 0.10 and 0.11. This is McFadden's pseudo-R2 and it may not be the best measure of fit. The VWLS (variance-weighted least squares) R2 is obtained by using the inverse of the estimated variances in the heteroscedastic model as weights in the corresponding regression model.
